Abstract

Bacillus pumilus is characterized by a higher oxidative stress resistance than other comparable industrially relevant Bacilli such as *B. subtilis* or *B. licheniformis*. In this study the response of *B. pumilus* to oxidative stress was investigated during a treatment with high concentrations of hydrogen peroxide at the proteome, transcriptome and metabolome level. Genes/proteins belonging to regulons, which are known to have important functions in the oxidative stress response of other organisms, were found to be upregulated, such as the Fur, Spx, SOS or CtsR regulon. Strikingly, parts of the fundamental PerR regulon responding to peroxide stress in *B. subtilis* are not encoded in the *B. pumilus* genome. Thus, *B. pumilus* misses the catalase KatA, the DNA-protection protein MrgA or the alkyl hydroperoxide reductase AhpCF. Data of this study suggests that the catalase KatX2 takes over the function of the missing KatA in the oxidative stress response of *B. pumilus*. The genome-wide expression analysis revealed an induction of bacillithiol (Cys-GlcN-malate, BSH) relevant genes. An analysis of the intracellular metabolites detected high intracellular levels of this protective metabolite, which indicates the importance of bacillithiol in the peroxide stress resistance of *B. pumilus*.

Introduction

Bacillus pumilus is a Gram-positive, rod-shaped and endospore-forming bacterium closely related to the industrially relevant bacteria *Bacillus subtilis* and *Bacillus licheniformis*. *B. pumilus* represents a potential alternative host for the industrial production of enzymes. For the evaluation and optimization of fermentation processes with this organism a comprehensive knowledge on its physiology and stress adaptation is required.

During fermentation processes a variety of stresses (e.g. salt, heat and oxidative stress) can impair the fitness of the production host and the quality of the fermentation product [1–3]. *B. pumilus* strains are highly resistant against UV radiation and hydrogen peroxide, which may explain the finding of viable spores of *B. pumilus* in hostile environments such as the interior of the Sonoran desert basalt and spacecrafts [4,5]. This natural potential and resistances of *B. pumilus* could be a major benefit for the

improvement of industrial production strains, since oxidative stress can occur in all phases of fermentation processes [1–3].

Reactive oxygen species (ROS) such as superoxide ($O_2^{\cdot-}$), hydrogen peroxide (H_2O_2) and hydroxyl radical ($OH\cdot$) are successive one-electron-reduction products of molecular oxygen and therefore occur in all aerobically living organisms [3,6,7]. Increased ROS production that exceeds the cell defense capacity leads to oxidative stress in the cell and to the oxidation of nucleic acids, proteins and lipids [2,3,8–10].

In *B. subtilis*, the cellular defense against oxidative stress is ensured by the detoxification of harmful agents, protection of macromolecules and the repair or removal of damaged molecules. The oxidative stress response of this organism is regulated by specific transcriptional regulators, such as PerR, SigB, LexA/RecA, Spx and OhrR, as previously described in detail [11–13]. The oxidative stress response of *B. pumilus* differs significantly from the response in *B. subtilis*, as major oxidative stress genes of *B.*

subtilis are missing in the genome of *B. pumilus*, such as the catalase KatA or alkyl hydroperoxide reductase AhpCF. For some of these genes no homologs could be found in the *B. pumilus* genome. This leads to the questions, which genes compensate the missing genes and are thus responsible for the oxidative stress resistance of *B. pumilus*. In this study we used a combination of proteomics, transcriptomics and metabolomics to investigate the individual peroxide stress response of *B. pumilus*.

Materials and Methods

2.1 Strain, Media, Growth and Cell Sampling

Bacillus pumilus Jo2 (DSM 14395) was used for all experiments described in this study. Cells were grown aerobically at 37°C and 180 rpm in minimal medium containing 15 mM (NH₄)₂SO₄, 8 mM MgSO₄×7 H₂O, 27 mM KCl, 7 mM Na-citrate×2 H₂O, 50 mM Tris-HCl (pH 7.5) supplemented with 1.8 mM KH₂PO₄, 2 mM CaCl₂, 1 μM FeSO₄×7 H₂O, 10 μM MnSO₄×4 H₂O, 4.5 mM glutamate, 0.2% w/v glucose and 0.04 μM biotin. Exponentially growing cells at an OD_{500 nm} of 0.6 were exposed to a final concentration of 2 mM hydrogen peroxide. Proteome samples were taken from unstressed cultures before and 10 as well as 30 minutes after exposure to hydrogen peroxide. Samples were pulse-labeled with L-[³⁵S]-methionine for 5 min, as described by Hoi *et al.* [14]. Samples for preparative gels were prepared from unlabeled cells 30 and 60 min after exposure to H₂O₂ [14]. Preparative gels were used only for spot identification via mass spectrometry.

Samples for RNA extraction were taken before (control) and 3 and 8 min after addition of H₂O₂. Cell samples for RNA extraction were mixed with 0.5 volumes of ice-cold killing buffer (20 mM Tris-HCl pH 7.5, 5 mM MgCl, 20 mM NaN₃), and immediately harvested at 10000×g for 5 min at 4°C.

2.2. Scanning Electron Microscopy

For the scanning electron microscopy, the cells were separated from the culture medium by filtration through a 0.2 μm pore size polycarbonate filter. The filter were placed in fixation solution (1% glutaraldehyde, 4% paraformaldehyde, 50 mM NaN₃ in 5 mM HEPES [pH 7.4]) for 1 h at room temperature and 4°C overnight. After fixation, the samples were treated with 2% tannic acid for 1 h, 1% osmium tetroxide for 2 h, 1% thiocarbohydrazide for 30 min, 1% osmium tetroxide overnight, and 2% uranyl acetate for 30 min with washing steps in between. The samples were dehydrated in a graded series of aqueous ethanol solutions (10–100%) and then critical point-dried. Finally, filter were mounted on aluminum stubs, sputtered with gold/palladium and examined in a scanning electron microscope EVO LS10 (Carl Zeiss microscopy GmbH, Oberkochen, Germany).

2.3 Transmission Electron Microscopy

Cells were fixed in 1% glutaraldehyde, 4% paraformaldehyde, 50 mM NaN₃ in 5 mM HEPES for 1 h at room temperature and then at 4°C overnight. Subsequent to embedding the cells in low gelling agarose, cells were postfixated in 2% osmium tetroxide for 2 h at 4°C. After dehydration in graded series of ethanol (20–100%) for 10 min each step with 0.5% uranyl acetate in 70% ethanol for 30 min (at 4°C) in between, the material was embedded in Epon. Sections were cut on an ultramicrotome (Reichert Ultracut, Leica UK Ltd, Milton Keynes, UK), stained with uranyl acetate and lead citrate and analyzed with a transmission electron microscope LEO 906 (Carl Zeiss microscopy GmbH, Oberkochen, Germany).

2.4 2D-Gel Electrophoresis

Cytosolic protein extracts were loaded onto IPG-strips in the pH-range 4–7 (GE Healthcare Bio-Sciences AB, Finland) using 100 μg protein for labeled samples and 500 μg for preparative gels. 2D-PAGE was performed as described by Büttner *et al.* [15]. Autoradiography of radioactively labeled gels was performed as previously described [14]. Preparative gels were stained with Coomassie Brilliant Blue as described by Voigt *et al.* [16]. Proteins were excised from preparative gels, digested and the peptide solution spotted onto MALDI targets using the Ettan Spot Handling Workstation (GE Healthcare, UK). Identification was performed using MALDI-TOF-MS/MS (Proteome Analyzer 5800 MDS Sciex, USA) and an in-house *B. pumilus* Jo2 (DSM 14395) database as described by Wolf *et al.* [17]. Protein quantification was done with the Delta2D proteome software (Decodon, Germany).

2.5 Microarray Experiment

Total RNA of *B. pumilus* was prepared by the acid phenol method [18] with the modifications described elsewhere [19]. The isolated RNA was treated with DNase (RNase-free DNase Set, Qiagen, Germany) and subsequently concentrated and cleaned (RNA cleanup and concentration Kit, Norgen Biotek, Canada). Quantity of RNA was determined on a microscale spectrophotometer (Nanodrop ND-1000, Peqlab Biotechnologie GmbH, Germany) and RNA integrity was analyzed using a capillary electrophoresis system (Bioanalyzer 2100, Agilent Technologies, USA). Synthesis and purification of fluorescently labeled cDNA was carried out according to Schroeter *et al.* [20] with minor modifications described below. After the labeling and clean-up step [20], 600 ng of respective Cy3- and Cy5 -labeled cDNA were admixed (ad. 44 μl), denaturated and mixed with 11 μl pre-warmed blocking agent and 60 μl hybridization buffer (both Gene expression hybridization kit, Agilent Technologies, USA). 100 μl of the emerging cDNA mixture, respectively, were used for any hybridization. Custom-made *B. pumilus* Jo2 4×44 K gene expression microarrays were obtained from Agilent Technologies (<https://earray.chem.agilent.com/earray/>), containing 60-mer Oligonucleotide probes (SurePrint technology, Agilent Technologies). Probe design was performed on the chromosome sequence of *B. pumilus* Jo2 (Sequence Intellectual Property of Henkel KGaA). In addition to the annotated open reading frames (ORFs), ORFs were predicted using (i) Glimmer 3.0 [21], (ii) ZCURVE [22], (iii) Genemark HMM [23], and (iv) Prodigal [24]. Predicted ORFs were added to the design provided that: (i) they were non-overlapping with existing ORFs; or (ii) they were in the reverse complementary strand of existing ORFs. On the annotated and predicted ORFs, up to 5 probes were designed. Altogether, a total of 41377 probes were designed by means of OligoWiz 2.1.3 [25] using default parameters for prokaryotic long-mers. The arrays were hybridized and washed according to the manufacturer's instructions (Two-Color Microarray-Based Gene Expression Analysis Protocol, Agilent Technologies, USA), followed by a last wash step with acetonitrile (Carl Roth GmbH+Co. KG, Germany) for 30 sec. Microarrays were scanned using the Agilent scanner Type G2565CA with high resolution upgrade G2539A and the software Scan Control 8.4.1 (Agilent Technologies, USA). Data were extracted from scanned images using Agilent's Feature Extraction Software (version 10.5.1.1; Agilent Technologies, USA) using default settings. A common reference type of design was employed, and data from three biological replicate hybridizations for each point in time were used for data analysis. Spot signals were normalized using Lowess as described earlier [26]. Next, for each ORF a signal was determined by taking the median signal of

the up to 5 probes per ORF. Differential regulation was determined from the biological triplicate measurements by false-discovery rate (FDR) from the Cyber-T p-values [27] by means of multiple testing correction [26]. Differential regulation was defined as a 2-fold or higher differential expression with a FDR cut-off value of 0.05 or lower.

2.6 Metabolomic Analysis of Thiols as their Monobromobimane-derivatives

Cells were grown in minimal medium as described above and exponentially grown cells from 10 ml culture medium were harvested before oxidative stress, 10, 30 and 60 min after addition of hydrogen peroxide. The isolation of LMW-thiols for HPLC analysis was performed as described previously [28]. In brief, after centrifugation the cells were washed with 50 mM Tris-HCl (pH 8.0) and resuspended in 50% acetonitrile containing 20 mM Tris-HCl (pH 8.0), 1 mM penicillamine as internal standard and 2 mM monobromobimane (mBBr). Control samples were resuspended without penicillamine and 5 mM N-ethylmaleimide (NEM) was used prior to addition of mBBr. Thiols were extracted at 60°C and directly labeled with mBBr. Labeling reaction was stopped with aqueous methane sulfonic acid in a final concentration of 5 mM. BSMB (monobromobimane-derivative of BSH) standards were synthesized as described previously [7,29]. For detection and quantification of LMW-thiols, ion pairing HPLC was performed as described before [30]. For absolute quantification the ratio peak area thiol/peak area internal standard was used and an eight-point calibration between 10 nM and 2000 nM was generated.

2.7 Prediction of the PerR Consensus Sequence

Prediction of the PerR consensus sequence was done with the PRODORIC® database (<http://prodoric.tu-bs.de/vfp/index2.php>) release 8.9 [31] using the consensus sequence as described by Fuangthong *et al.* [32].

Results and Discussion

3.1 Effects of H₂O₂ on Growth and Cell Morphology

Exponentially growing *B. pumilus* cells were treated with 2 mM hydrogen peroxide. Thus, the concentration of H₂O₂ that was used to trigger the stress in this study was about 40-fold higher than those used for comparable analyses with *B. subtilis* or *B. licheniformis* [13,20]. The highest peroxide concentrations allowing growth for *B. subtilis* and *B. licheniformis* were 4 and 1 mM, respectively (Table S1). *B. pumilus* is still able to grow with 20 mM hydrogen peroxide. This indicates a striking resistance of *B. pumilus* against peroxide stress. Compared to unstressed cells, growth was significantly impaired for a short time (approximately 15 min) after the H₂O₂ treatment (Figure 1). However, after that time, cells continued to grow for about one hour. An electron microscopy analysis indicated that after exposure to H₂O₂ most of the cells are morphologically intact, but some of the cells exhibited major damage of their envelope (Figure 2D). Furthermore, scanning electron microscopy revealed some atypically long cells (up to approximately 10–20% two hours after H₂O₂ treatment, Figure 2B, 2E) indicating an impact of hydrogen peroxide on processes involved in cell division.

3.2 Global Expression Profile

All values presented for up- and downregulation of genes or proteins are fold change values. The analysis of the soluble intracellular proteome of *B. pumilus* revealed 54 significantly upregulated and 111 downregulated proteins 10 min after H₂O₂

treatment (with a threshold of 2-fold, Table 1, Table S2, Figure 3). For the visualization of the fast and early response on proteome level, a labeling with ³⁵S-methionine was necessary. 30 minutes after initiating the stress, 73 proteins were up- and 59 proteins downregulated (Table 1, Table S2 and S3, Figure 4). Transcriptome analysis revealed an at least 2-fold increased transcription of 181 genes three minutes after treatment with H₂O₂; 76 of them were more than 3-fold upregulated. Eight minutes after treatment, the transcription of 558 genes appeared at least 2-fold increased (307 genes with an at least 3-fold increased transcription). Three minutes after the stress, 266 genes were transcribed with an at least 3-fold lower rate than under control conditions, for 296 genes this decreased transcription rate was shown eight minutes after treatment. To indicate quality of the transcriptome results, raw data for individual probes for selected genes (which were not found to be induced in the proteome analysis) are presented in Table S4. These data show similar basal values and changes following addition of hydrogen peroxide for all five probes corresponding to a gene.

To compare the physiological changes in H₂O₂ treated *B. pumilus* cells with the oxidative stress responses of other organisms, the upregulated genes and proteins were assigned to putative regulons known from related organisms like *B. subtilis* and *B. licheniformis* [13,20]. 139 of the upregulated genes and proteins could be assigned to these putative regulons (Table S2). The thus classified genes and proteins identified in this study are summarized and discussed below.

3.3 PerR Regulon

The PerR regulon is known to be highly induced by oxidative stress caused by hydrogen peroxide and paraquat [13]. As shown previously for *B. licheniformis*, the *B. pumilus* genome encodes a PerR regulator protein with a high level of identity (93%) to the PerR-protein known from *B. subtilis* [20]. Transcription of the *perR* gene was significantly increased immediately after stress (Table 1). This indicates a regulation mechanism of PerR in H₂O₂ treated *B. pumilus* cells that is similar to the de-repression model reported for *B. subtilis* [33].

In our study genes assigned to a putative PerR regulon, including those encoding the regulator proteins *Fur* and *SpxA* as well as the zinc-uptake protein *ZosA*, the heme biosynthesis complex *HemABCD2LX* and the general stress protein *YjbC* were significantly induced at transcriptional level (Table 1).

Strikingly, some of the PerR-regulated genes exhibiting the highest induction in *B. subtilis* cells subjected to hydrogen peroxide, are absent from the genome of the *B. pumilus* strain used in our study, as well as from a previously published *B. pumilus* genome [34]. This applies e.g. for the genes encoding the catalase *KatA* and the DNA-protection protein *MrgA*. Furthermore, *B. pumilus* lacks not only the genes *ahpC* and *ahpF*, encoding subunits of the alkyl hydroperoxide reductase, but there are no genes annotated with this function in the genome.

Instead of *KatA*, a gene annotated as catalase *KatX2* (53% sequence similarity to *B. subtilis* *KatX*) was significantly induced in *B. pumilus* cells at transcriptional and translational level (up to 10 and 20-fold, respectively, Table 1). Thereby, *KatX2* was one of the proteins with the highest induction rates detected. *B. subtilis* and *B. licheniformis* subjected to hydrogen peroxide exhibit a more than 100-fold induction of *KatA* [13,20]. *KatX2* comprises about 0.38% of the cytoplasmic protein present in the gel before addition of hydrogen peroxide. The values for *B. subtilis* and *B. licheniformis* are 0.13% in both strains (personal communication C. Scharf, B. Voigt). After addition of hydrogen peroxide *KatX2* comprises about 3.8% of the cytoplasmic protein. This is comparable to the

Figure 1. Growth of *B. pumilus*. Growth of *B. pumilus* under control conditions (filled squares) and stressed with 2 mM H₂O₂ at OD_{500 nm} 0.6 (empty squares). doi:10.1371/journal.pone.0085625.g001

Figure 2. Electron microscopy micrographs. Scanning (A,B,E) and transmission (C,D) electron microscopy micrographs of *B. pumilus* cells under control conditions (A,C), 30 min (B,D) and 120 min after treatment with 2 mM H₂O₂ (E). doi:10.1371/journal.pone.0085625.g002

Selected genes and proteins that are induced in H₂O₂ treated *B. pumilus* cells.

Genes and proteins are listed, which could be assigned to putative regulons known from other *Bacilli*. Complete lists of upregulated as well as downregulated genes/proteins is given in supporting information Tables S2 and S3. For transcriptome, selected genes are shown for 3 and 8 minutes after stress compared to the control conditions (0 min). For a complete list of induced and repressed genes see Table S3. Differential regulation was determined from the biological triplicate measurements by false-discovery rate (FDR) from the Cyber-T p-values [27] by means of multiple testing correction [26]. Differential regulation was defined as a two-fold or higher differential expression with a FDR cut-off value of 0.05 or lower. Protein quantification was performed by the Delta 2D software (Decodon) from 3 biological replicates with a FDR cut-off value of 0.05 or lower. doi:10.1371/journal.pone.0085625.t001

value of 3.6% for *B. licheniformis* (personal communication B. Voigt) but higher than the value for *B. subtilis* (1.2%, personal communication C. Scharf). These values indicate that in *B. pumilus* there is a higher synthesis of KatX2 already in unstressed cells compared to *B. subtilis* and *B. licheniformis* KatA explaining the lower induction rate. In *B. subtilis*, KatX is the major spore catalase and under control of SigB and SigF [35,36]. We detected a *B. subtilis* PerR consensus sequence [32] containing 2 mismatches about 90 bases in front of the start codon of KatX2 indicating a possible involvement of PerR in its regulation.

3.4 Fur Regulon and Fe-metabolism

The PerR-regulated *fur* gene of *B. pumilus*, shows 95% similarity to the *fur* gene known from *B. subtilis* and was induced 3.6-fold after stress [32]. The regulator protein Fur of *B. subtilis* controls the expression of genes responsible for iron uptake [37]. Immediately after exposure to H₂O₂, cytosolic iron concentration is considerably reduced to prevent the formation of OH[•] by the Fenton reaction [13]. Upregulation of the Fur-controlled genes may be a reaction of the cells to optimize iron uptake in order to face the resulting iron limitation. Alternatively it might be that Fur is H₂O₂ sensitive as it is in *E. coli* [38].

Nine genes of a putative Fur regulon showed a significantly increased expression in *B. pumilus* cells after H₂O₂ treatment, including the ABC transporter system *shuB1C1G1* (Table 1). The *shuC* gene was induced by H₂O₂ in *B. subtilis* and *B. licheniformis*, too [13,20]. Further Fur regulon member genes known to be induced by H₂O₂ in *B. subtilis* showing an induction in our study were *ykuN*, *ykuP* (flavodoxins) and the hypothetical protein *ykuO*. With an about 30-fold higher mRNA level 8 minutes after treatment, these were among the highest upregulated genes in this putative regulon. The putative nitroreductase YfhC, also induced in H₂O₂ stressed *B. subtilis* cells, was the only member of the putative Fur regulon we observed to be upregulated at translational level.

The gene *ywjA*, encoding another ABC transporter of yet unknown function, the peptidase encoding gene *yfkM* and the bacillibactin esterase encoding gene *ybbA* were upregulated, too. These genes are Fur-regulated in *B. subtilis*, but they were not upregulated by H₂O₂ in this organism [13,39]. In *B. subtilis* and *B. licheniformis*, the siderophore biosynthesis complex encoded by *dhbACEBF* was strongly upregulated by H₂O₂. In our study, these genes showed no significant changes in their expression level.

Other genes that exhibited higher transcription rates after H₂O₂ treatment were the iron ABC transporter protein encoding gene *feuA* and its upstream-located regulator *ybbB* (renamed *btr* in *B. subtilis*) [40]. Unlike *B. subtilis*, the *B. pumilus* genome encodes a second Fhu-related iron uptake system. Our study showed an induction of the genes encoding FhuC2-FhuB2-BPJ35820 as well as *shuG2* and *shuD* immediately after subjecting the cells to the stress. Two further putative iron transporter systems, *bpj35830-bpj35840-bpj35850* and *bpj08420-bpj08430-bpj08440*, were induced, too. The proteins encoded by the latter genes showed no significant homology to any protein known from related *Bacillus* species.

Furthermore, the proteomic approach revealed a strong induction of the siderophore synthesis proteins RhbA, RhbE and RhbF, encoded by the *rhbABCDEF*-operon (Table 1). A rather slight induction at the translational level was shown for the iron/sulfur cluster biogenesis proteins SufB, SufS, SufD and SufC as previously shown for *B. licheniformis* [20]. The *sufU* gene was found to be only slightly upregulated at the mRNA level.

Figure 3. Cytosolic proteome 10 min after H₂O₂ treatment. The cytosolic proteome of *B. pumilus* cells 10 min after H₂O₂ treatment. Cell samples were labeled with L-[³⁵S]-methionine during the exponential growth phase (OD_{500 nm} 0.6), and 10 min after H₂O₂ addition. Proteins were separated in a pH gradient 4 (right) -7 (left). doi:10.1371/journal.pone.0085625.g003

3.5 Spx Regulon and Bacillithiol

Another regulator protein assigned to the putative PerR regulon is SpxA, controlling the expression of the Spx regulon in *B. subtilis*

[41,42]. This gene exhibited an about 4-fold increased transcription rate in H₂O₂ stressed *B. pumilus* cells. Some of the genes and proteins attributed to a putative Spx regulon in *B. pumilus*

Figure 4. Cytosolic proteome 30 min after H₂O₂ treatment. The cytosolic proteome of *B. pumilus* cells 30 min after H₂O₂ treatment. Cell samples were labeled with L-[³⁵S]-methionine during the exponential growth phase (OD_{500 nm} 0.6), and 30 min after H₂O₂ addition. Proteins were separated in a pH gradient 4 (right) –7 (left). doi:10.1371/journal.pone.0085625.g004

appeared to have rather moderately increased expression rates or were not induced after H₂O₂ treatment.

In our study we detected six genes of a putative Sp_x regulon to be induced following H₂O₂ treatment (Table 1). The proteins

encoded by three of them, nitro/flavin reductase NfrA, putative NADPH-dependent butanol dehydrogenase YugJ and thioredoxin-disulfide reductase TrxB, were induced in H₂O₂ treated cells, too. Upregulation of *msrAB* (methionine sulfoxide reductase

Figure 5. Concentration of thiol compounds in *B. pumilus* cells. Cytosolic concentration of bacillithiol (BSH), CoA and cysteine (Cys) per mg cell dry weight (CDW) during the exponential growth phase ($OD_{500\text{ nm}} 0.6$ at 0 min) and 10, 30 and 60 min after H_2O_2 treatment. doi:10.1371/journal.pone.0085625.g005

operon) and *trxA* (thioredoxin) was detected at transcriptional level only. The proteins TrxA and TrxB are described to act in direct detoxification of hydrogen peroxide [43–45]. Cystathionine gamma-lyase MccB and DinB-like domain-containing protein YuaE showed an induction only at proteome level.

The Spx-regulated *srf* operon, mediating competence and metabolic functions in *B. subtilis*, is absent in the *B. pumilus* genome as shown before for *B. licheniformis* [42,46,47].

We noticed an increased transcription of *ypdA* and *yqiW* as well as an induction of the *yphP* gene product (Table 1). These genes co-occur with bacillithiol (Cys-GlcN-malate, BSH) synthesis genes [48]. However, only one gene encoding a protein involved in bacillithiol synthesis, *yvjG* was transcribed at a slightly elevated level (Table S2). Bacillithiol is one of the major thiols in *B. subtilis* and known to be involved in resistance against organic peroxide stress and disulfide stress [7,49,50]. For further investigation, we analyzed the cytosolic metabolome of H_2O_2 treated *B. pumilus* cells concerning the concentration of thiol compounds. Our analysis revealed a bacillithiol level of 2.6 nmol per mg cell dry weight already under control conditions. Similar BSH concentrations have been detected in *B. subtilis* (0.6–2.2 nmol per mg) [7,48,51]. Ten minutes after H_2O_2 treatment, the cytosolic concentration of bacillithiol increased to 5 nmol per mg cell dry weight (Figure 5). The increase continued up to a concentration of about 6.2 nmol per mg cell dry weight 60 minutes after stress. Since only one bacillithiol synthesis gene (*yvjG*, renamed *bshB2* in *B. subtilis*) was slightly upregulated, increase of bacillithiol concentration in the cells might be regulated allosterically, for example, by an oxidation of the BSH pool leading to a relief of feedback inhibition. [52,53].

3.6 SOS Regulon

H_2O_2 treatment leads to the formation of OH^\bullet by Fenton reaction, which exhibits a high DNA-damaging potential. Lowering the concentration of iron in the cells reduces this threat. As a result, *B. subtilis* and *B. licheniformis* cells subjected to oxidative stress caused by H_2O_2 , induced the SOS regulon, regulated by the

proteins RecA and LexA, responsible for repair of DNA [13,20,54,55].

The proteomic analysis displayed the induction of two proteins, excinuclease subunit UvrB and the recombinase RecA, assigned to a putative SOS regulon in *B. pumilus* following H_2O_2 treatment (Table 1). The transcriptomic approach added further 13 upregulated genes belonging to this putative regulon; among them the excinuclease subunits encoding genes *uvrA* and *uvrC*. The operon *yneABynzC*, induced by H_2O_2 and involved in suppression of cell division in *B. subtilis*, was also strongly induced in our study [13,56]. This might be an explanation for the formation of atypically long cells as described above. Showing an about 44-fold increased transcription rate, *yneA* belongs to the strongest induced genes observed in our study. Furthermore, the putative DNA double-strand break repair cluster *yhaONM* exhibited a significantly higher transcription rate following H_2O_2 addition [57].

3.7 CtsR Regulon

The CtsR regulon, mediating repair and/or degradation of misfolded and damaged proteins, was induced by several oxidative stressors in *B. subtilis* and *B. licheniformis* [13,20,58]. In our study, we detected an upregulation of nine genes assigned to a putative CtsR regulon in *B. pumilus* indicating a significant impact of H_2O_2 on protein quality (Table 1). The operon *ctsR-mcsAB-clpC* was transcribed with significantly higher intensity after the addition of H_2O_2 as well as the genes *clpE*, *clpX* and *clpP*, encoding members of the proteolytic complex. Only ClpP was observed to be induced at the protein level. Furthermore, the DNA repair protein encoding gene *radA* and the DNA integrity scanning protein encoding gene *disA* showed higher transcription rates compared to control conditions.

3.8 SigB Regulon

Besides the induction of the above described putative regulons more or less directly associated to oxidative stress, H_2O_2 treated cells exhibited an upregulation of 47 genes known to be under control of the general stress sigma factor SigB in *B. subtilis* (Table 1)

[59,60]. A part of a putative SigB-regulon in *B. pumilus* detected to be upregulated in our study was the *sigB* gene itself with its signal cascade genes *rsbRSTUVW* and *rsbX* indicating an activation of the putative regulon via the general stress response cascade known from *B. subtilis* [61].

Another of these putative SigB-dependent genes, encoding the putative universal stress protein NhaX, showed the highest induction rate detected in this study (more than 60-fold). Further strongly upregulated genes are the regulator protein encoding gene *mgsR* and *ydaG* (general stress protein), both also detected to be induced in H₂O₂ stressed *B. licheniformis* cells [20]. The upregulated genes *mgsR* and *ydaG* encode proteins with still unknown functions. Six of the upregulated putative SigB-dependent genes could be also detected to be induced in the proteomic approach. The putative general stress protein YtxH is among the strongest induced proteins (about 14-fold). The putative iron storage/DNA protecting protein Dps, providing peroxide resistance in *B. anthracis*, was induced in H₂O₂ treated *B. pumilus* cells, too [62].

3.9 CymR Regulon

The results of our study showed an upregulation of several proteins belonging to a putative CymR regulon. In *B. subtilis*, it is described to be involved in regulation of the sulfur metabolism [63]. An induction of genes belonging to this regulon has been shown in cells afflicted with oxidative stress caused by paraquat, but not stress caused by H₂O₂ [13]. Our proteome study showed a strong induction of three putatively CymR-regulated proteins. The adenylyl-sulfate kinase (CysC) was with an induction of about 24-fold the strongest induced protein. An upregulation of the sulfate adenylyltransferase (Sat) catalyzing sulfate assimilation to 3'-phospho-adenylylsulfate was also detected (Table 1). Further proteins involved in cysteine biosynthesis were not significantly upregulated. The third upregulated protein is the uroporphyrin-3 C-methyltransferase (CysG). This enzyme catalyzes a reaction in a branch in the heme pathway producing precorrin2. An induction of the enzymes that continue the pathway from precorrin2 to siroheme could not be detected.

3.10 Other *B. pumilus* Upregulated Genes/proteins

The OhrR-regulated peroxiredoxin-encoding gene *ohrA* is reported to be involved in organic peroxide resistance in *B. subtilis* [64]. Following H₂O₂ treatment, there was no induction of this gene observed in *B. subtilis* and *B. licheniformis* [13,20]. In our study, we observed a strongly induced expression of this gene at transcriptional and translational level indicating an involvement of this peroxiredoxin in the H₂O₂ resistance of *B. pumilus* (Table 1). Transcription of the other organic peroxide resistance peroxiredoxin (*ohrB*) as well as their regulator gene *ohrR* was also slightly induced in hydrogen peroxide treated *B. pumilus* cells.

H₂O₂ treatment induced some additional regulator genes. One of them is *fadR*, encoding a regulator protein mediating fatty acid degradation in *B. subtilis* [65]. Two genes putatively controlled by FadR, *etfAB* - encoding the electron transfer flavoprotein alpha and beta subunit, were also induced (Table S2). Another regulator, AbrB1, controlling the expression of genes induced by transition from exponential to stationary growth in *B. subtilis* [66], was induced at transcriptional and translational level. Similar results, but with significantly higher induction rates in the proteomic approach, were observed for the AbrB1-regulated peroxiredoxin YkuU and thiol-disulfide oxidoreductase YkuV. Furthermore, several putative regulator genes with still unknown targets were observed to be upregulated. *Bpj13620*, *bpj17020* and *ycdI* showed the highest changes in their expression rates. Genes encoding a

sensor kinase and a response regulator forming the two-component system YhcYZ were significantly induced directly after H₂O₂ treatment. Its function is also unknown.

Several genes and proteins involved in transport processes were detected to be upregulated following H₂O₂ stress (Table 1, S2). H₂O₂ treatment caused an upregulation of the sodium uptake system *natAB* and the *mrpABCDEFGF* cluster. This operon encodes a sodium excretion system that is considered to be the major sodium excretion system in bacteria and acts in pH homeostasis and multiple resistances in *B. subtilis* [67,68].

Strikingly, transcription of the glycine betaine uptake system consisting of *opuAA-AB-AC* and *opuCA-CB-CC-CD* was observed to be significantly induced after treatment, indicating that H₂O₂ impacts osmotic homeostasis in *B. pumilus* cells [69]. Furthermore, it is worth to mention that H₂O₂ induced expression of a putative TRAP regulon in *B. pumilus* cells. An upregulation of the tryptophan-synthesis operon *trpABFCDE* as well as histidinol-phosphate aminotransferase HisC was observed in our analysis. However, neither addition of tryptophan nor addition of glycine betaine before peroxide treatment brought forth better growth or survival of stressed *B. pumilus* cells (data not shown).

3.11 Downregulated Genes/proteins

As shown for many other organisms, the adaptation mechanism of *B. pumilus* cells to oxidative stress includes also a downregulation of vegetative cellular functions. Most of the down-regulated genes encode proteins involved in main metabolic pathways. As shown for *B. subtilis* and *B. licheniformis*, expression of the purine and pyrimidine synthesis genes was downregulated as well as genes involved in synthesis of arginine (Table S3) [13,20]. Contrary to *B. subtilis* and *B. licheniformis*, a repression of histidine synthesis genes was not observed. Instead, isoleucine and leucine synthesis genes were expressed in lower amounts following H₂O₂ treatment. This repression might due to the iron sparing response described by Gaballa et al. [70]. Repression of enzymes involved in branched chain amino acid synthesis has been found during iron starvation in *B. subtilis* [37]. Furthermore, we observed a reduced expression of most of the aminoacyl-tRNA-synthetases, with the exception of tryptophanyl-tRNA-synthetase *trpS*, which matched the upregulation of the tryptophan operon.

Strikingly, a stringent response, i.e. a downregulation of ribosomal proteins or elongation factors like *fusA*, *tsf* or *tufA*, as described for other organisms (*B. subtilis*, *B. licheniformis*, *E. coli*) could not be detected in *B. pumilus* [13,20,71].

Conclusion

The combination of proteomics and transcriptomics revealed a specific adaptation of *B. pumilus* cells caused by the oxidative stress trigger H₂O₂. Although many of the induced genes and proteins could be assigned to well-known oxidative stress regulons like PerR, CtsR and Fur, there are particular mechanisms detectable which seem to be involved in the remarkable oxidative stress resistance of *B. pumilus*. The concentration of H₂O₂ that was used to trigger the stress in our study was about 40-fold higher than those used for comparable analysis of *B. subtilis* or *B. licheniformis*. Our study could enlighten several points at which the peroxide stress response of *B. pumilus* cells is different from its Gram-positive relatives. It is suggested that the catalase KatA is replaced by the catalase KatX2. Furthermore, our study revealed an induction of genes that are highly correlated to bacillithiol synthesis indicating an involvement of bacillithiol in the peroxide stress response of *B. pumilus*. Metabolome analysis demonstrated a basal level of this protective metabolite but also an increase of the cytosolic

bacillithiol concentration during peroxide stress. Furthermore, a considerable set of H₂O₂ induced unique proteins with so far unknown function could be identified in this study. These proteins are worth to address in follow up studies to elucidate their specific role in the oxidative stress adaptation of this organism. Finally, since *B. pumilus* is an organism of industrial interest, understanding its oxidative stress response and defining marker genes for the analysis of fermentation processes is important to prevent possible negative influences on the process and the product quality.
